Introduction:

This report contains a summary of 1983 air quality data obtained by continuous monitoring instruments for gases at 109 stations, and hi-volume samplers for particulate matter at 164 stations. Wind and temperature data from 24 locations are also summarized.

Summaries of the hourly averaged data for sulphur dioxide, soiling index, carbon monoxide, hydrocarbons (total, reactive and methane), ozone, total reduced sulphur, nitrogen dioxide, nitric oxide, nitrogen oxides, wind direction, air temperature, vertical temperature gradient and Air Pollution Index as well as the daily measured data for total suspended particulate matter, lead, iron, copper, cadmium, chromium, zinc, manganese, nickel, vanadium, sulphate and nitrate obtained at these monitoring locations are given in this report.

For several years the measured ambient gas and particulate data were published first in bound volumes and more recently on microfiche. By 1983, the annual database had grown to approximately 8,000,000 data points. A survey by the Air Quality Assessment Unit showed that users of the Ontario Air Quality database required either (a) a large amount of data in magnetic tape format, (b) statistical summaries in hardcopy, or (c) small subsets of the database in hardcopy. In short, there was no identified need for transcription of the entire database from soft to hard storage. Publication of the data also presented difficulties when the inevitable post-publication errors were discovered in the database and several pages of "errata" had to be produced and distributed. Consequently, the expense and effort which were expended on the publication of the raw data will, in future, be redirected to increasing the scope of the air pollution statistics and introducing air quality trends into the Annual Air Quality Monitoring Report.

Requests for the Air Quality Monitoring Report, or subsets of the data in hardcopy or magnetic tape should be directed to: The Air Quality Unit, Air Resources Branch, Ontario Ministry of the Environment, Toronto, Ontario.

Sampling Stations:

Table 1 lists the stations in the Ontario monitoring network with continuous hourly sampling instruments. The first eight columns give the region in which the monitor is located, the station identification number and name, its bearing on the Universal Transverse Mercator (UTM) grid projection, the survey type, the elevation of the station above mean sea level and the height of the air intake above ground. The remaining seven columns indicate the pollutants — total reduced sulphur (TRS), sulphur dioxide (SO_2), soiling index (COH), ozone (O_3), carbon monoxide (CO), hydrocarbons (HC), and nitrogen oxides (NO_x) — monitored at that station. The survey type indicates whether a station is oriented toward a specific source (S) or for general ambient air quality (A). N indicates the site was nonconforming to the Canadian Federal-Provincial criteria for monitor siting to such a degree that resulting data may not be strictly comparable with results at other monitoring locations.

The locations of continuously monitoring stations for Metropolitan Toronto, Hamilton, the Sudbury area, and Windsor are shown in Figures 1, 2, 3 and 4 respectively.

Table 2 lists the stations in the Ontario monitoring network for suspended particulate matter using the hi-volume sampling method. The first eight columns give the region in which the monitor is located, the station number and name, the survey type, the UTM grid coordinates, the station elevation and air intake height. These columns are the same as those in Table 1. The survey type consists of a letter indicating the survey purpose, either oriented towards a specific source (S) or for general ambient air quality (A). N indicates the site was nonconforming to the Canadian Federal-Provincial criteria for monitor siting to such a degree that resulting data may not be strictly comparable with other monitoring results, and the numeral

indicates sampling frequency — daily (1), once every three days (3) or once every six days (6). The remaining three columns indicate those analyses performed on the exposed filter that are herein reported: total suspended particulate matter (TSP), one or more of the metals, lead, iron, zinc, copper, cadmium, chromium, vanadium, nickel, and manganese, and sulphate and nitrate ($\text{SO}_4^{2-}/\text{NO}_3^-$).

The location of monitors in Metropolitan Toronto, Hamilton and Windsor are shown in Figures 1, 2 and 4 respectively.

Table 3 outlines the stations with meteorological sampling instrumentation. The first six columns are as described above for continuous and hi-volume sampling. The next column gives the sensor type: WS — wind speed, WD — wind direction, T — ambient temperature or DT — temperature gradient. The numeral indicates the general level of the sensor (1 = low, 2 = middle, 3 = high). The last column gives the sensor height in meters.

Criteria for Desirable Ambient Air Quality:

When pollutants are released into the ambient air, they may have a significant adverse effect on man, animals, vegetation or property. In order to determine at what concentration significant adverse effects occur, Ontario employs a permanent standards setting committee. The committee, comprised of experts in several fields, reviews the scientific literature and recommends concentrations and averaging times for the air quality criteria. The desirable ambient air quality criteria are set at the lowest concentration causing a known significantly adverse effect. These criteria, therefore, serve as a convenient yardstick by which the Province may estimate its success in achieving in concentration causing a known significantly adverse effect. These criteria, therefore, serve as a convenient yardstick by which the Province may estimate its success in achieving its goals for desirable ambient air quality through emission controls.

Table 4 outlines the criteria for desirable ambient air quality for those contaminants contained in this report. The criteria are given in units of parts per million by volume of air, parts per billion by volume of air, coefficient of haze (COH) per 1000 feet of air or micrograms per cubic metre of air for the sampling time appropriate for each criterion: 1 hour, 8 hours, 24 hours or 1 year.

1983 Measurements:

Validation and processing of air quality data in Ontario is the responsibility of the Air Quality and Meteorology Section of the Air Resources Branch. The instrumentation, however, has been installed and maintained by the Technical Support Group in each of the six Regional Offices. Analysis of hi-volume filters is done in the Ministry's Laboratory Services and Applied Research Branch.

Continuous monitoring data are acquired in two ways. Data from stations in major population centres and those areas which have a publicized Air Pollution Index are telemetered in real-time to the central data-acquisition facility at the Air Resources Branch in Toronto where they are digitized, stored on magnetic tape, and then computer-processed into the Air Quality Information System (AQIS). All other data are recorded locally on analog charts which are later read and digitized by the Air Quality Unit, and then processed by computer for entry into the AQIS files in the same way as the telemetered data.

Exposed filters from the high-volume sampling network are collected by the Regions and are sent to the Laboratory Services and Applied Research Branch. There, the total suspended particulate concentration is determined, and any required analyses for the components of the particulate matter are performed. Data are then stored in the Laboratory's Sample Information System (SIS) and, at intervals, abstracted from the SIS files to the AQIS files.

In this Volume, the annual summaries of hourly readings of continuous monitoring and daily measurements of hi-volume results for each station and contaminant are reported. Each line gives the station number and location, the number of days, hours or samples for which valid data were obtained, the percentile distribution, and, where appropriate, the number of times the air quality criteria were exceeded. For continuous monitoring results, the arithmetic mean, maximum 1-hour concentration and maximum 24-hour concentration are also reported. (In the case of carbon monoxide, the maximum 8-hour concentration is reported instead of the 24-hour concentration.) For the hi-volume results, the arithmetic mean, geometric mean and maximum 24-hour concentrations are reported. The reported percentiles (10, 30, 50, 70, 90 and 99) indicate the cumulative frequency distribution for that pollutant. That is, the concentration reported is that concentration which is not exceeded X% of the time. For example, if the 70 percentile for SO_2 is .010 ppm, this means that the concentration of SO_2 did not exceed .010 ppm on 70% of the hours reported for this site.

Meteorological data and the Air Pollution Index are summarized by the number of hours of data reported in various categories or by mean and percentiles depending upon the most appropriate method of reporting the data.

Only those stations which report valid readings on 6570 hours for continuous 1-hour monitoring, and 40 samples for hi-volume monitoring during 1983 are considered to have an adequate sample size from which to determine a representative annual mean. For those stations reporting fewer than the required number of samples, the reported arithmetic or geometric mean cannot be considered as representative for the comparison with the annual criterion for sulphur dioxide, soiling index or total suspended particulate matter.

Analyses of Data:

Sulphur Dioxide: (See Table 5)

When fuels containing sulphur are burned or ores containing sulphur are smelted, the sulphur joins with the oxygen in the air to form sulphur oxides. Sulphur dioxide (SO_2) is the major sulphur oxide produced in these processes. It is a heavy, pungent, colourless gas which easily combines with water vapour to form sulphurous acid (H_2SO_3) or with oxygen to form sulphur trioxide (SO_3). Both sulphurous acid and sulphur trioxide may further react to form sulphuric acid (H_2SO_4) — a major component of acid rain.

The gaseous sulphur oxides (SO_2 and SO_3) have been associated with human respiratory illness, vegetation damage, and the weathering of materials. In the acid or acid salt form (sulphate or sulphite), the sulphur oxide can adversely affect respiratory health, vegetation or materials, and cause reduction of visibility through the atmosphere. Sulphur oxides also are a major factor in increasing the acidity of precipitation.

Of the 70 stations in the Ontario network, only one recorded an annual mean above the annual criterion of 0.02 ppm: Niagara Falls Rd./Ontario St., Thorold (0.022). This station is located near an industrial source of SO_2 .

Most of the stations which exceeded either the 1-hour or the 24-hour criterion on more than one occasion were located in the vicinity of major industrial sources of SO_2 . The station measuring the highest 24-hour average (0.82 ppm) was Niagara Falls Rd./Ontario St., Thorold. The highest 1-hour average (2.27 ppm) was also measured at Niagara Falls Rd./Ontario St., Thorold. Twenty-two stations reported exceedences of the 1-hour criterion of 0.25 ppm. The most exceedences (125) occurred at Niagara Falls Rd./Ontario St., Thorold. Eleven stations exceeded the 24-hour criterion at least once.

Carbon Monoxide: (See Table 6)

Carbon monoxide (CO) is produced during the incomplete combustion of hydrocarbon fuels. In terms of total weight and concentration, it leads all other contaminants in city

air. Mobile sources, mainly cars, trucks and buses, are almost exclusively responsible, accounting for over 90% of all CO emissions. Pollutant control equipment on automobiles has been the main method used in reducing CO emissions in Ontario.

When CO is inhaled, it enters the bloodstream through the lungs and binds chemically to hemoglobin, the substance which transports oxygen to the cells of the body. Because CO is bound to the hemoglobin instead of oxygen, less oxygen is available for transport to the muscles and organs. With less oxygen available to the heart, there is a reduction in the amount of blood pumped through the body and therefore the amount of oxygen available to the body is further reduced. In a person with heart disease, the effects of excessive carbon monoxide can be hazardous. Those persons with respiratory disorders such as emphysema may also be severely affected.

The highest concentrations of carbon monoxide were measured at 381 Yonge St. in Toronto. This station, located close to a major traffic artery and with the urban street canyon, measured an annual average of 3.8 ppm, a maximum 8-hour average of 21 ppm and a 1-hour maximum of 29 ppm. The 8-hour criterion of 13 was exceeded 16 times at this station. All stations met the 1-hour criterion of 30 ppm.

Hydrocarbons: (See Tables 7, 8 and 9)

Hydrocarbons are emitted naturally from trees and other vegetation and in the decay of animal and plant material. They are also emitted by motor vehicles, gasoline storage tanks and many industrial sources such as the petroleum and chemical industries. The non-methane fraction of the total hydrocarbons is of special interest because it reacts with the nitrogen oxides in the atmosphere in the presence of sufficient sunlight to form ozone and other oxidant chemical species.

Three types of measurement of hydrocarbons are made in Ontario: methane, reactive (non-methane) hydrocarbons and total hydrocarbons. The instrumentation used employs flame ionization detection techniques to determine the total hydrocarbon concentration as well as the methane concentration and the reactive (non-methane) hydrocarbon concentration in parts/million of carbon.

No criterion have been set for desirable ambient concentrations of total hydrocarbons, reactive hydrocarbons or methane. The highest annual mean for total hydrocarbons was reported at Bronte Rd./Woburn Cres., Oakville: 2.73 ppm. The highest annual mean methane concentration (1.64 ppm) occurred at Cheapside Rd./Walpole Conc. 5, Nanticoke and the highest annual reactive hydrocarbon concentration occurred at Walpole South P.S., Nanticoke (0.40 ppm).

No monitoring station measured all three types of hydrocarbons over a full year.

Ozone: (See Table 10)

Ozone is a naturally occurring constituent of the upper atmosphere where it plays an important role in the maintenance of life on the ground by absorbing harmful ultraviolet radiation. In the lower atmosphere, ozone is detrimental to the health of man and plants and causes damage to some materials. Unlike most other pollutants, however, ozone is generally not directly emitted into the atmosphere by specific sources. Instead, it is the product of chemical reactions in the presence of adequate sunlight between reactive hydrocarbon compounds and nitrogen oxides.

Ozone is the main constituent of the Los-Angeles-type smog which, along with other photochemical oxidants and peroxyacetyl nitrate (PAN), have been associated at high concentrations with adverse effects on human health. Ozone may irritate the lining of the nose and throat and hinder the functioning of the lungs. Many plants, especially some varieties of commercial crops such as white bean and tobacco, may be severely injured or killed by high concentrations of ozone.

Since time is required for the photochemical reactions to produce ozone, the highest concentrations are often found some distance downwind from the source of nitrogen oxides and reactive hydrocarbons. In addition, ozone is capable of travelling long distances through the atmosphere. Thus, ozone formed in the Mississippi or Ohio River Valleys in the United States may reach Ontario. This long-range transport of ozone has become a major area of concern in recent years.

Ozone transport and formation are both very dependent upon large-scale weather conditions, therefore year-to-year average concentrations as well as the number of criterion exceedences may be quite variable. Ozone concentrations are also seasonally dependent with highest concentrations occurring during the late spring and summer. Therefore, annual mean concentrations are of lesser importance than the number of hours the 80 ppb criterion is exceeded. The only stations which did not exceed the 1-hour criterion in 1983 were located in Northern Ontario (Thunder Bay, Hawkeye Lake and Mission). Stations reporting more than 120 exceedences of the criterion were located at Long Point Provincial Park (169) and Simcoe (182).

The maximum 1-hour concentration was measured at Lawrence/Kennedy, Scarborough: 0.159 ppm. The maximum 24-hour O_3 average was measured at Simcoe: 0.089 ppm.

Total Reduced Sulphur: (See Table 11)

Much of the total reduced sulphur (TRS) measured in Ontario is in the form of hydrogen sulphide (H_2S). In the vicinity of pulp and paper mills and refineries, however, significant concentrations of mercaptans and other reduced sulphurs may be present. Reduced sulphur compounds are also released from swamps, bogs and marshes as the result of anaerobic decay processes.

The reduced sulphurs are objectionable because of their unpleasant odour at very low concentrations (often less than 30 ppb). Silver and copper tarnish and lead-based paints blacken in the presence of H_2S .

Maximum concentrations of total reduced sulphur for a 1-year average (4.9 ppb), 24-hour average (70 ppb) and 1-hour average (254 ppb) occurred at 262 Church St., Fort Frances. The majority of stations, most of which monitor near industry, reported maximum concentrations in excess of 60 ppb. No criteria have yet been set for TRS although a guideline of 27 ppb for a 1-hour average has been set for measurements made in the vicinity of Kraft paper mills. All such monitors exceeded the guideline.

Nitrogen Dioxide (See Table 12)

Nitrogen dioxide (NO_2) is one of a number of nitrogen oxide compounds which are formed both by man and nature. The main natural sources in the lower atmosphere are lightning and soil bacteria. Nitrogen and oxygen from the atmosphere are also combined during high temperature combustion such as occurs in automobile engines, power plants, incinerators and many chemical processes to form nitrogen dioxide.

Nitrogen dioxide in high concentrations may have a detrimental effect on the respiratory system especially to those with chronic lung disease. Nitrogen dioxide may also react with hydrocarbon compounds in the presence of sunlight to form ozone and other photochemical pollutants (See section on Ozone) or react with water to form nitric acid, a component of acidic precipitation, which may affect health and corrode materials.

Nitrogen dioxide was measured at 31 sites in Ontario in 1983. The maximum annual mean NO_2 concentration was 0.040 ppm at 381 Yonge St. in Toronto. The maximum 1-hour (0.18 ppm) concentration occurred at both Junction Triangle in Toronto and Evans/Arnold Ave. in Etobicoke

while the maximum 24-hour concentration (.010) occurred at Bathurst/Wilson, North York. There were no exceedences of the 1-hour (.020) or 24-hour (.010) criteria.

Nitric Oxide: (See Table 13)

Nitric oxide (NO), like nitrogen dioxide, is formed by natural sources such as lightning and bacteria and by high-temperature combustion of fossil fuels such as automobile engines. In the latter formation, it is nitric oxide which is formed first and, when in high concentration and in the presence of oxygen or hydrocarbons, oxidized further to nitrogen dioxide.

No evidence exists that nitric oxide at the concentrations measured in the ambient atmosphere has any direct adverse effect on health and welfare. However, with its conversion to NO_2 , the effects previously mentioned may occur.

Nitric oxide is measured at 32 sites in Ontario. The maximum annual mean concentration of nitric oxide, 0.084 ppm, was measured at Bathurst/Wilson, North York. The maximum 1-hour concentration was recorded at Edna/Frederick St., Kitchener: 0.94 ppm. The maximum 24-hour average of 0.37 ppm was reported at Bathurst/Wilson, North York. Both of these sites are located near a major expressway.

Nitrogen Oxides: (See Table 14)

Nitrogen oxides, the sum of nitrogen dioxide and nitric oxide concentrations, are measured at 32 sites. The maximum annual concentration of 0.117 ppm occurred at 381 Yonge St. in Toronto. The maximum 1-hour (1.01 ppm) and 24-hour (0.41 ppm) concentrations occurred at Kitchener and Bathurst/Wilson, North York respectively.

Suspended Particulate Matter:

Traditionally, air pollution has been identified by the public with black or dark smoke. Improved combustion technology and a switch to cleaner-burning fuels have eliminated most of the sooty particles causing the darkness of the smoke. Suspended particulate matter is still, however, the most visible of air contaminants. The composition varies considerably with time, place and season and may contain soil particles, organic matter or compounds containing sulphur, nitrogen, chlorine or metals such as lead.

Suspended particulate matter or its constituents may cause the corrosion or soiling of materials, a decrease in sunlight or atmospheric visibility, damage to vegetation or adverse effects on human or animal health.

There are many sources of suspended particulate matter, both natural and man-made. Fine particles of dust from combustion, incineration, construction, mining, metals smelting and processing, grinding processes, agriculture and transportation constitute much of man's contribution. Natural sources include wind-blown soil, forest fires, ocean spray and volcanic activity. When the particulate matter is emitted into the atmosphere, most of the larger particles fall to the ground close to their source while the smaller ones may travel distances as great as thousands of kilometres with the wind before settling to the surface. It should be noted, however, that, based on estimates made in the United States, only 5% of the total particulate matter released into the atmosphere comes from controllable sources; the remaining 95% come from natural and fugitive sources.

Suspended particulate matter is measured by either the hi-volume method or the soiling index method in the Ontario network. The hi-volume method collects particles on a glass-fibre filter over a 24-hour period and the sampler is run on a once a day, once every three days or once every six days sampling cycle. The soiling index method samples on a paper tape for one hour and is run continuously.

Soiling Index: (See Table 15)

The soiling index is a relative measure of suspended particulate matter in the size range of particles which most easily enter the lungs. In this method, the soiling properties of the particulate matter deposited upon a paper tape filter are measured by the reduction of light transmitted through the soiled filter. The amount of reduction in transmission is related to the quantity, opacity and darkness of the deposited particles. The evaluation is carried out on a 1-hour sampling of air. The unit of measure for soiling index is the Coefficient of Haze (COH) per 1000 feet of air sampled.

36 stations reported soiling index for a 1-hour sampling period in 1983. The maximum annual mean was reported at Bathurst/Wilson, North York: 0.57 COH/1000 ft. Three sites, Sherbourne/Wilton, Toronto; North Park, Hamilton; and Bathurst/Wilson, North York, exceeded the annual criterion of 0.50 COH/1000 ft.

The maximum 24-hour average (1.9 COH/1000 ft.) was measured at both Bathurst/Wilson, North York and Barton/Wentworth, Hamilton, API backup. Twenty-one monitoring sites reported 24-hour averages in excess of the 24-hour criterion of 1.0 COH/1000 ft. but only seven did so more than 10 times: Bathurst/Wilson, North York (39); North Park, Hamilton (34); Barton/Wentworth, Hamilton API backup, (15); Barton/Wentworth, Hamilton (13); Sherbourne/Wilton, Toronto (13); 467 University Ave. W., Windsor (12); and 467 University Ave. W., Windsor API backup (12).

Total Suspended Particulate Matter (See Table 16)

Total suspended particulate matter (TSP) was measured at 164 sites in Ontario in 1983. Daily monitoring was performed at 26 sites, once every three day monitoring at 32 sites and once every six days monitoring at 106 sites.

The maximum annual geometric mean for TSP occurred at 185 Queen St. S., Thorold: 111 micrograms per cubic meter ($\mu\text{g}/\text{m}^3$). The annual criterion of $60 \mu\text{g}/\text{m}^3$ (geometric mean) was exceeded at 24 sites.

The maximum 24 hour concentration was measured at Stelco North, Nanticoke: $379 \mu\text{g}/\text{m}^3$. One hundred and sixteen stations reported exceedences of the daily criterion of $120 \mu\text{g}/\text{m}^3$. The most exceedences at a daily monitoring station were 75 at North Park, Hamilton; at a once in three-day station: 34 at Bonney St. Pumphouse, Sault Ste. Marie; at a once in six-day station: 25 at 185 Queen St. S., Thorold.

Sulphate in Suspended Particulate Matter: (See Table 11)

Sulphates (SO_4^{-2}) are formed by the oxidation of sulphur trioxide which when combined with water vapour forms sulphuric acid (H_2SO_4). The sulphuric acid may then combine with ammonia or some other anion to form a sulphate compound.

Many different sources emit sulphur, or sulphur compounds into the atmosphere. Natural sources of sulphur include sea spray, bacterial decomposition, volcanoes and forest fires. Anthropogenic sources include the burning of fuels containing sulphur (such as coal and oil), the smelting of sulphur-containing metals and the refining of petroleum.

The sulphate compounds, especially the acid forms, have been linked to respiratory irritation and disease, corrosion of materials, reduction of visibility and the formation of acidic precipitation.

Sulphate concentrations reported here are derived from the particulate matter collected on glass-fibre filters. It has been found that artifact sulphates form on glass-fibre filters from ambient SO_2 and that reported sulphate concentrations are therefore artificially high. No attempt has been made to correct the data reported here. Caution should be taken in interpreting absolute concentrations. Relative comparison among samples or stations is likely less affected.

The highest annual arithmetic mean for particulate sulphate concentrations (15.7 micrograms per cubic metre) was reported at Bonney St. Pump House, Sault Ste. Marie

as was the maximum measured concentration for 24-hours ($166.3 \mu\text{g}/\text{m}^3$).

Nitrate in Suspended Particulate Matter: (See Table 18)

Nitrogen oxide compounds, formed from atmospheric nitrogen and oxygen under high temperature combustion, photochemical reactions or bacterial action may react with other compounds in the air to form nitrate (NO_3^-) or nitric acid (HNO_3).

Natural sources of nitrogen oxides or nitrates include lightning, biological agents, sea spray or photochemical reactions. Anthropogenic sources include all high-temperature combustion processes, transportation and fertilizer production and usage. Nitrate and nitric acid are involved in corrosion of materials, visibility degradation and acidic precipitation. They may also be an adverse factor on human health.

Particulate nitrate is collected in the Ontario network on glass-fibre filters. Studies have shown that, like sulphates, artifact nitrates are formed on this filter medium. There remains some uncertainty as to the degree of artifact formation. The data reported herein are unaltered and user caution is recommended in interpreting absolute concentrations.

The maximum annual arithmetic mean concentration of particulate nitrates, $5.1 \mu\text{g}/\text{m}^3$, was reported at Mississauga Public Library and Bramalea Fire Hall. The maximum measured 24-hour concentration was $23.0 \mu\text{g}/\text{m}^3$ at North Park, Hamilton.

Lead in Suspended Particulate Matter: (See Table 19)

Because of its many useful properties, lead has been utilized by man since antiquity. The health hazards of this metal have also been long recognized. The concern over these hazards focused during the 19th and 20th century on death and serious illness caused mainly by the ingestion of lead. With the near elimination of lead poisoning as a cause of death in the past two decades, attention now has turned to the more subtle adverse health effects of exposure to lead such as impairment of mental functions.

Much of the particulate lead emitted into the atmosphere results from the combustion of gasoline containing lead additives. Other sources of lead particles include the secondary smelting of lead, battery manufacture, metal fabrication (brass, bronze and solder), some paint and glass manufacture and the production of iron, steel, copper and nickel. Since 1972, there has been a reduction in the lead content of gasoline. This reduction coupled with the introduction of lead-free gasoline in 1975 has resulted in a decrease in the amount of lead emitted from gasoline usage in Ontario.

The lead concentration on the hi-volume filters is determined by either X-ray fluorescence or atomic absorption spectrophotometry.

Maximum lead concentrations are found in the vicinity of lead processing plants in the Metropolitan Toronto area. These operations have been under special intensive study since 1973. The maximum annual average concentration ($2.6 \mu\text{g}/\text{m}^3$) and the highest single 24-hour measurement ($32.3 \mu\text{g}/\text{m}^3$) both occurred at 2414 Dixie Rd., Mississauga. The 24-hour criterion of $5.0 \mu\text{g}/\text{m}^3$ was exceeded 110 times across this network. The most exceedences (50) were registered at 2414 Dixie Rd., Mississauga.

The maximum concentrations at the stations not near lead processing plants are found at stations monitoring close to major traffic arteries. The maximum annual average concentration was recorded at Bathurst/Wilson, North York ($0.7 \mu\text{g}/\text{m}^3$) as was the highest daily measurement ($3.3 \mu\text{g}/\text{m}^3$). None of these sites measured lead concentrations in excess of the $5.0 \mu\text{g}/\text{m}^3$ criterion.

Iron in Suspended Particulate Matter: (See Table 20)

Iron particles are among the most abundant of the heavy metals emitted into the air. Major sources include iron ore

processing, steel manufacturing, incineration, coal burning, smelting of other metals and road dust. Iron is also released as a result of the weathering of iron/steel materials such as the rusting of automobiles. Natural sources of iron particles include volcanoes and terrestrial dust from the weathering of rocks and soil.

The analysis of the iron content of particulate is performed by atomic absorption spectrophotometry (AA) or induced coupled plasma techniques (ICP).

The maximum annual arithmetic mean for particulate iron occurred at Bonney St. Pumphouse, Sault Ste. Marie: 6.5 ug/m³. The maximum 24-hour concentration was measured at Burlington/Leeds, Hamilton: 19.3 ug/m³.

Nickel in Suspended Particulate Matter: (See Table 21)

The maximum 24-hour concentration for nickel occurred at Killaly East/James, Port Colborne: 1.480 ug/m³ as did the highest annual arithmetic mean concentration (1.158). There were no exceedences of the 24-hour criterion (2.0 ug/m³) during 1983.

Copper in Suspended Particulate Matter: (See Table 22)

The 95 Inkerman St., Guelph monitor recorded the highest annual average concentration of particulate copper in 1983 (0.92 ug/m³). The highest 24-hour concentration was 3.43 ug/m³ collected at the Experimental Farm, Simcoe, well below the Ontario criterion of 50.0 ug/m³.

Recent studies have shown that copper measurements may be affected by contamination of the sample by the motor on the sampling device. This contamination is highest when a new motor is installed and decreases with motor age. No attempt has been made to correct the data for this effect.

Cadmium in Suspended Particulate Matter: (See Table 23)

The maximum 24-hour concentration, 0.380 ug/m³, was measured at 3050 Lakeshore Blvd., Etobicoke, as was the maximum annual average: 0.016 ug/m³. The criterion of 2.0 ug/m³ for a 24-hour average was not exceeded.

Chromium in Suspended Particulate Matter: (See Table 24)

The Lasco Hopkins St. S., Whitby monitor recorded the highest annual average chromium concentration in 1983: 0.021 ug/m³. The highest 24-hour measurement in the Province, 0.545 ug/m³, was at 3050 Lakeshore Blvd. West, Etobicoke. The criterion of 1.5 ug/m³ for a 24-hour average was not exceeded.

Zinc in Suspended Particulate Matter: (See Table 25)

The highest annual average zinc concentration (1.0 ug/m³) and the maximum 24-hour value (7.0 ug/m³) were recorded at Lasco Hopkins St. S., Whitby.

Manganese in Suspended Particulate Matter: (See Table 26)

The maximum manganese concentration for a 1-year average (0.480 ug/m³) occurred at Bonney St. Pump House, Sault Ste. Marie. The highest 24-hour measurement (1.530 ug/m³) occurred at Lasco Hopkins St. S., Whitby. The 24-hour criterion was not exceeded.

Vanadium in Suspended Particulate Matter: (See Table 27)

The highest annual average concentration for particulate vanadium, 0.014 ug/m³, occurred at Sarnia, Cornwall and Thunder Bay. No exceedences of the 2.0 ug/m³, 24-hour average criterion were measured in 1983.

Ontario's Air Pollution Index (See Tables 28 and 29)

Despite the best efforts of pollution control, the emission of

contaminants into the air cannot be totally eliminated without bringing all man's activities to a halt. Whenever pollutants are released to the atmosphere, the potential exists for the buildup of concentrations to unacceptable levels during weather conditions which are unsuitable to their dispersion or removal (e.g. light winds, limited vertical mixing depth). Since it is economically unrealistic, and often impossible, to control emissions so that under no circumstances will pollution concentrations approach critical levels, there is a need for an alert system to warn of increasing pollution concentrations.

The Air Pollution Index (API) was introduced in Ontario in 1970 to protect the public from air pollution episodes caused by emissions under adverse weather conditions. Two pollutants, sulphur dioxide and suspended particulate matter, were chosen for the Index based upon the results of health studies during severe air pollution episodes. These studies showed a definite correlation between illness and high concentrations of SO₂ and TSP. The API was thus devised as a basis for action in an alert system to control or prevent an air pollution episode caused by these two pollutants. Legislation in Ontario authorizes the Minister of the Environment to order any source not essential to public health and safety to curtail or cease its operations when pollutant concentrations which may be injurious to health are reached.

The Ontario API is calculated from the average SO₂ concentration and average soiling index for the preceding 24 hours. Hourly concentrations of these pollutants are measured in each city where an Index is reported and sent via the Ontario Air Quality Telemetry Network to the Air Resources Branch office in Toronto. There, a computer calculates the 24-hour averages and the resulting API which is released to the public. Whenever the API reaches critical levels, the Duty Meteorologist is informed, and based upon his forecast of continuing adverse weather conditions, action may then be taken by Regional Abatement Officers.

If the API reaches 32, and the Duty Meteorologist forecasts a continuation of adverse weather conditions for the next six hours, an "Air Pollution Advisory" is issued. At this time, significant sources of SO₂ and particulate matter are advised to curtail operations.

The "First Alert" level occurs at an API of 50 with meteorological conditions expected to continue for at least six hours. Major sources may be ordered by the Minister to curtail operations.

If abatement action does not succeed in stopping the rise in API, or if weather conditions worsen, a "Second Alert" is issued at 75. With a forecast of continued adverse weather, the Minister may order further curtailment.

At 100, an "Air Pollution Episode Alert" is issued and, again with a forecast of six hours of adverse weather conditions, all non-essential sources may be ordered to shut down their operations by the Minister. At this level, the pollution concentrations may have an effect on healthy individuals and may seriously endanger the health of those with severe cardiac or respiratory disease.

The Air Pollution Index Alert System was first introduced in Toronto on March 23, 1970. Since that time it has expanded to other Ontario cities: Hamilton in June 1970, Sudbury in January 1971, Windsor in March 1971, Happy Valley in May 1971, Welland in January 1974, Niagara Falls in November 1974, Coniston in February 1975, New Sudbury in March 1976, Sarnia in December 1977 and St. Catharines in September 1979. The Happy Valley API was terminated in January 1975, and the Welland API was terminated in October 1978.

The maximum recorded API in the Province in 1983 occurred on Jan. 22 in New Sudbury when an Index of 63 was reached. This was the only city to exceed 50 during 1983. The Advisory Level of 32 was reached on 3 occasions in Toronto and once each in Hamilton, Sudbury, Windsor and New Sudbury.

An API of 15 or less is considered as "Very Good" air quality: 16-31 is considered "Good"; 32-49 is considered "Moderate"; 50-99 is "Poor" air quality and 100 or greater is "Very Poor". A summary of the number of hours in each of

these categories is given in Table 28. The majority of hours are in the "Very Good" designation for all locations.

The history of the Index stations — the maximum level and the number of times the Index has equalled or exceeded 32 and 50 for the years 1970 to 1983 are given in Table 29.

Wind: (See Table 30)

The Ontario monitoring network includes 24 wind sensors. They are installed to have the best possible exposure practical at each site. There are instances, however, where monitor siting may not conform to the recommended criteria of the World Meteorological Organization or the Canadian Atmospheric Environment Service.

The wind direction data are partitioned into an eight-point compass, North, Northeast, East, Southeast, South, Southwest, West and Northwest. No direction is defined during periods when the wind speed is less than 5.0 kilometers per hour. These are reported as hours of calm conditions. The frequency of "Calm" conditions is also given in Table 30.

Wind speed data are stored in AQUIS but they are not summarised here.

Ambient Air Temperature: (See Table 31)

Eight sites in the Ontario network measure ambient air temperature at the lowest level of the tower. Data are

reported for annual minimum, maximum and mean and the number of hours occurring in each of seven temperature ranges.

Vertical Temperature Differences: (See Tables 32 and 33)

The vertical temperature difference between the lowest level of each of the eight monitoring towers and either the mid level (Level 2 — Level 1) or upper level (Level 3 — Level 1) are given in Tables 32 and 33 respectively. The number of hours occurring in each of 7 or 8 categories are reported along with the annual mean difference. The temperature difference when divided by the distance between the two temperature sensor (the column labeled 'Height Difference') provides an approximate measurement of the thermal stability of the atmosphere termed the temperature gradient. A temperature gradient of less than -0.017 Celsius degrees per meter is indicative of an unstable atmosphere, a condition generally conducive to rapid mixing and dilution of pollutants in the air. Values between -0.017 and 0.015 Celsius degrees per meter are indicative of a neutrally stable atmosphere, a state conducive to moderate mixing and dilution. Temperature gradients greater than 0.015 Celsius degrees per meter characterize a stable atmosphere, a state associated with poor mixing and diffusion. Positive temperature gradients which reflect an atmospheric state in which air temperatures increase with height (warm air over cold air) is commonly referred to as a temperature inversion, or, simply, an inversion.

LEGEND

Survey Type:

- A — Ambient survey for general air quality
- S — Source-specific survey
- N — Station does not conform to Canadian Federal Provincial siting criteria
- 6 — Ambient particulate levels measured every 6 days
- 3 — Ambient particulate levels measured every 3 days
- 1 — Ambient particulate levels measured daily

Analysis:

TSP: Filter analyzed for total suspended particulate matter

Metals: Filter analyzed for one or more of the following metals by atomic absorption, X-ray fluorescence or induced coupled plasma methods: lead, iron, copper, cadmium chromium, zinc, vanadium, nickel, manganese, cobalt.

SO₄⁻²/NO₃⁻: Filter analyzed for sulphate and nitrate ions.

Legend: WS1 — wind speed below 23 m; WD1 — wind direction below 23 m;
 WS2 — wind speed 23 m to 76 m; WD2 — wind direction 23 m to 76 m;
 WS3 — wind speed above 76 m; WD3 — wind direction above 76 m;
 T — ambient temperature; DT1 — temperature difference
 Level 2 minus Level 1; DT2 — temperature difference Level 3 minus Level 1.

Table 4 **Criteria for Desirable Air Quality**
(per O. Reg. 872/74)

NAME OF CONTAMINANT	UNIT OF MEASUREMENT	AVERAGE AMOUNT OF CONCENTRATION	PERIOD OF TIME	APPROXIMATE EQUIV. AT 10°C AND 101.2 KPa PRESSURE
Carbon Monoxide	Parts of carbon monoxide per one million parts of air by volume	30	1 hour	36,200 ug/m ³
		13	8 hours	15,700 ug/m ³
Nitrogen Dioxide	Parts of nitrogen dioxide per one million parts of air by volume	0.20	1 hour	400 ug/m ³
		0.10	24 hours	200 ug/m ³
Ozone	Parts of ozone per one billion parts of air by volume	80	1 hour	165 ug/m ³
Soiling	Coefficient of Haze per 1000 feet of air	1.0	24 hours	—
		0.5	1 year	—
Sulphur dioxide	Parts of sulphur dioxide per one million parts of air by volume	0.25	1 hour	690 ug/m ³
		0.10	24 hours	275 ug/m ³
		0.02	1 year	55 ug/m ³
Cadmium	Micrograms of cadmium per cubic metre of air	2.0	24 hours	
Chromium	Micrograms of chromium per cubic metre of air	1.5	24 hours	
Copper	Micrograms of copper per cubic metre of air	50.0	24 hours	
Lead	Micrograms of lead per cubic metre of air	5.0	24 hours	

Table 4 — Continued ...

NAME OF CONTAMINANT	UNIT OF MEASUREMENT	AVERAGE AMOUNT OF CONCENTRATION	PERIOD OF TIME
Manganese	Micrograms of manganese per cubic metre of air	50.0	24 hours
Nickel	Micrograms of nickel per cubic metre of air	2.0	24 hours
Total Suspended Particulate Matter	Micrograms of total suspended particulate matter per cubic metre of air	120 60 (geo-metric mean)	24 hours 1 year
Vanadium	Micrograms of vanadium per cubic metre of air	2.0	24 hours

Table 5

Summary of Data: Sulphur Dioxide (all values in p.p.m.)

Ontario Criteria — 1 Hour Average: 0.25 p.p.m.; 24-Hour Average: 0.10 p.p.m.; 1 Year Average: 0.02 p.p.m.

INS — Indicates insufficient sample size to apply 1 Year average criterion.
